

# Project Proposal

November 7, 2022

**Team Member Names: Madeline Witters**

**Project Title:**

## **Problem Statement**

One of the most important metrics of success in any business is customer retention. A business's customer churn rate can have very significant financial impacts that effect the company in a multitude of ways. A [Harvard Business Review article](#) recently stated that merely increasing a company's customer retention rates by 5% can increase profits upwards of 25%; conversely, the cost of obtaining a new customer can be anywhere from 5 to 25 times as expensive as retaining an existing one.

It therefore follows that if a company is able to predict which customers are at risk of leaving, they can use this information to better position themselves in a variety of ways, such as: creating an intervention plan for customers at risk of leaving, calculating potential loss of revenue in the next quarter, or simply better understanding their customer demographic and various market segments.

In this project, there are two central research questions that I will aim to answer:

1. Can I create a model that will predict customer churn with a reasonable accuracy rate?
  - Furthermore, does one model type outperform another in predicting customer churn?
2. What features/customer attributes (present in the dataset) are most important in predicting whether a customer will churn?

## **Data Source**

For this project I am using the "Bank Customer Churn" dataset, sourced from Kaggle. The dataset has 10,000 data points and 12 variables. Each row represents an individual customer. Variables are both categorical and quantitative, and include demographic variables (age, gender, country), as well as industry-specific variables (balance, credit\_card, etc.). The response variable "churn" is categorical, containing a 1 if the client left the bank and a 0 if they remained a customer.

## **Methodology**

My methodology will consist of three distinct parts:

- Exploratory Data Analysis
- Variable Selection
- Modeling

## **Exploratory Data Analysis**

Exploratory data analysis will consist of any necessary data cleaning (addressing missing data, removing unnecessary/not relevant variables, one hot encoding, scaling/standardization, etc.), outlier detection, and examination for potential collinearity between predictor variables. As part of this step, I also plan to do some basic visual analysis of the distribution of predictor variables via boxplots, histograms, or density plots. Finally, I will partition the dataset into a train/test split.

## Variable Selection

For variable selection, I plan to use Lasso or Elastic Net to identify the most relevant features, as I anticipate some features will not contain predictive power. I will select the best  $\lambda$  parameter for Lasso/Elastic Net via cross-validation. Depending on the results from my analysis, I may also examine the “most important” features from the Random Forest model, and consider fitting my final model(s) to those chosen variables.

## Modeling

I plan to build and compare two classification models: a logistic regression model and a random forest.

Logistic regression lends itself well to this dataset in two ways: it can be easily used for binary classification/prediction, and it is also very interpretable (meaning we can extract information about which attributes have the most predictive power). This is especially important for business-related data, as oftentimes one needs to explain the results from a model to non-technical stakeholders. Furthermore, the fact that the response data can be represented in terms of a probability is particularly appealing. While I will use cross-validation to identify the optimal threshold for classification, one can imagine a scenario where a business may prefer to set their own threshold and/or have the model directly report the probability that a customer may leave, rather than a binary indicator.

Second, I plan to contrast the logistic regression model with a random forest. While random forests do not have the interpretability of logistic regression, and are known as being a bit more of a “black box” model, they are also known for their predictive prowess. I think it will be interesting to contrast the performance of these two models and see which achieves better predictive performance. As mentioned in the variable selection section, I also plan to examine the “most important” features from the Random Forest model and compare those to the variables chosen by Lasso/Elastic Net. If different subsets of variables are chosen, I may build 4 models total (logistic regression fit to Lasso/Elastic Net variables, logistic regression fit to Random Forest most important, Random Forest fit to Lasso/Elastic Net, Random forest fit to Lasso/Elastic Net variables), and compare and contrast performance.

Finally, if I have time, I may also build and compare a third classification model, such as a support vector machine or k-nearest neighbors model. If I choose to build this additional model, I will of course discuss and compare its performance with that of the logistic regression and random forest models. I will also discuss pros/cons of using each model and when it may be appropriate to use one above another.

## Evaluation and Final Results

I will evaluate and compare the models in a variety of ways. The primary evaluation method will be by examining the classification error rate for the test data. Related to this, I may also construct a confusion matrix and/or AUC-ROC curve.

#note: perhaps discuss additional metrics to be examined: pseudo  $R^2$ , AIC/BIC ?

Second, I will also provide an interpretation of results with respect to the final chosen variables. This is especially relevant for this project, as businesses are often hoping to gain insight into *why* customers are leaving. Examination of the variables include in the final models can be relevant to addressing this question (e.g. are younger customers more at risk of leaving?).

#note: add more to this section on how you will examine/discuss variables

I will finally discuss how one could use the results from my project to design their own study, as well as how the project could be improved.

#note: discuss additional models to test, variables that could be added, etc.
